Program a Game Engine from Scratch

Mark Claypool

Development Checkpoint #9

Sprite Animation

4.12.5 Using Sprites

At this point, the game programmer can load sprites into the ResourceManager in a few simple steps. The first step is to create a sprite file, such as the one in Listing 3.3 on page 18. The second is to load the sprite into the ResourceManager so the game can make use of it. Example code to load the saucer sprite for Saucer Shoot (Section 3.3) is shown in Listing 3.2 on page 17.

To actually use Sprites, say to draw them in an animated fashion on the window, Dragonfly needs to be extended in a couple of ways. A Sprite holds the “static” properties of an animation in that they are fixed for all Objects that use the sprite. To actually animate the Sprite, an Animation class is created to provide control of the Sprite animation for each associated Object.

Animation is shown in Listing 4.130. The class needs Sprite.h as well as <string>. The attribute m_p_sprite indicates what Sprite is associated with the Animation and m_name the corresponding name. The attribute m_index keeps track of which frame is currently being drawn. The attribute m_slowdown_count is a counter used in conjunction with the Sprite slowdown rate (see Section 4.12.2 on page 148) to provide animation through cycling the frames. Methods to get and set each attribute are also provided. The setSprite() methods also sets the bounding box for the Object (described in the upcoming Section 4.13.2).

Listing 4.130: Animation.h

```cpp
// System includes.
#include <string>

// Engine includes.
#include "Sprite.h"

class Animation {

private:
  Sprite *m_p_sprite; // Sprite associated with Animation.
  std::string m_name; // Sprite name in ResourceManager.
  int m_index; // Current index frame for Sprite.
  int m_slowdown_count; // Slowdown counter.

public:
  // Animation constructor
  Animation();

  // Set associated Sprite to new one.
  // Note, Sprite is managed by ResourceManager.
  // Set Sprite index to 0 (first frame).
  void setSprite(Sprite *p_new_sprite);

  // Return pointer to associated Sprite.
  Sprite *getSprite() const;

  // Set Sprite name (in ResourceManager).
  void setName(std::string new_name);

  // Get Sprite name (in ResourceManager).
  std::string getName() const;
};
```
The Animation `draw()` method, shown in Listing 4.131, basically makes a call to Sprite `draw()` then advances the sprite index to the next frame. Line 12 asks the Sprite to draw the current frame at the indicated position. The block of code at line 15 checks if the sprite slowdown count is set to -1 – if so, this indicates the animation is frozen, not to be advanced, so the method is done. Otherwise, the slowdown counter is advanced, and on line 24 checked against the slowdown value to see if it is time to advance the sprite frame. Advancing increments the index, with the code starting at line 31 taking care of looping from the end of the animation sequence to the beginning. The last two actions at the end of the method set the slowdown counter and the sprite indices to their values for the next call to `draw()`.

Listing 4.131: Animation draw()

With Frame, Sprite and Animation defined, Object can be extended to support sprite animations. The Object is provided with an Animation object (\texttt{m\_animation}) with corresponding \texttt{setAnimation()} and \texttt{getAnimation()} methods, and a method to set the associated sprite (\texttt{setSprite()}). Up until now, game objects needed to define their own \texttt{draw()} methods to display something on the window. But with a Sprite now associated with an Object, the \texttt{draw()} method can now be defined to draw the animated sprite.

Listing 4.132: Object class extensions to support Sprites

```cpp
private:
    Animation m\_animation; // Animation associated with Object.

public:
    // Set Sprite for this Object to animate.
    // Return 0 if ok, else \(-1\).
    int setSprite(std::string sprite_label);

    // Set Animation for this Object to new one.
    // Set bounding box to size of associated Sprite.
    void setAnimation(Animation new\_animation);

    // Get Animation for this Object.
    Animation getAnimation() const;

    // Draw Object Animation.
    // Return 0 if ok, else \(-1\).
    virtual int draw();
```

The revised Object \texttt{draw()} method shown in Listing 4.133 method simply calls the Animation \texttt{draw()} method, passing in the Object position.

Listing 4.133: Object \texttt{draw()}

// Draw Object Animation.
// Return 0 if ok, else -1.
int Object::draw()
    pos = getPosition()
    return m_animation.draw(pos)

Note, draw() is still defined as virtual. This allows a derived class (a game object) to define its own draw() method, should it so choose. In such a case, the game object’s draw() would get called. The game programmer could write code for object-specific functionality (say, displaying a health bar above an avatar), and still call the built-in Object draw() explicitly, via Object::draw().

The setSprite() method is shown in Listing 4.134. The first block of code retrieves the Sprite by name (sprite_label) from the Resource Manager, checking that the Sprite can be found. Then, the Sprite is associated with the m_animation object.

Listing 4.134: Object setSprite()

4.12.6 Development Checkpoint #9!

Continue Dragonfly development, getting the engine to support Sprites. Steps:

1. Create an Animation class, following Listing 4.130 and stubbing out the methods. Make sure that it compiles, first. Then, implement the methods to get and set the simple attributes

2. Next, implement Animation draw() as per Listing 4.131 testing it carefully.

3. Extend the Object class to support Sprites, as per Listing 4.132.

4. Write the code for the revised Object draw() in Listing 4.133 that uses Animation to draw. Write code for a game object (inherited from Object) that associates with a Sprite. Integrate this game object into a game and test the functionality of the Object draw(). Debugging can be visual (what is seen on the screen), but use logfile messages to help determine when/where there are problems.

5. Test a variety of game objects with a variety of Sprites (from the Saucer Shoot tutorial or created by hand). Verify the Sprites can be advanced, slowed down and stopped and are drawn without visual glitches. Test and debug thoroughly before proceeding.
